(54) Title: HIV INTEGRASE INHIBITORS

(57) Abstract: The present invention relates to the inhibition of HIV integrase, and to the treatment of AIDS or ARC by administer-
ing compounds of the following formula, or a tautomer of said compound, or a pharmaceutically acceptable salt, solvate or prodrug
thereof: (formula I) wherein R¹, R² and B¹ are as defined herein.

HIV INTEGRASE INHIBITORS

Background

10 Human immunodeficiency virus (HIV) has been identified as the etiological agent responsible for acquired immune deficiency syndrome (AIDS), a fatal disease characterized by destruction of the immune system and the inability to fight off life threatening opportunistic infections. Recent statistics (UNAIDS: Report on the Global HIV/AIDS Epidemic, 15 December 1998), indicate that as many as 33 million people worldwide are infected with the virus. In addition to the large number of individuals already infected, the virus continues to spread. Estimates from 1998 point to close to 6 million new infections in that year alone. In the same year there were approximately 2.5 million deaths associated with HIV and 20 AIDS.

There are currently a number of antiviral drugs available to combat the infection. These drugs can be divided into three classes based on the viral protein they target and their mode of action. In particular, saquinavir, indinavir, ritonavir, nelfinavir and amprenavir are 25 competitive inhibitors of the aspartyl protease expressed by HIV. Zidovudine, didanosine, stavudine, lamivudine, zalcitabine and abacavir are nucleoside reverse transcriptase inhibitors that behave as substrate mimics to halt viral cDNA synthesis. The non-nucleoside reverse transcriptase inhibitors, nevirapine, delavirdine and efavirenz inhibit the 30 synthesis of viral cDNA via a non-competitive (or uncompetitive)

mechanism. Used alone these drugs are effective in reducing viral replication. The effect is only temporary as the virus readily develops resistance to all known agents. However, combination therapy has proven very effective at both reducing virus and suppressing the 5 emergence of resistance in a number of patients. In the US, where combination therapy is widely available, the number of HIV-related deaths has declined (Palella, F. J.; Delany, K. M.; Moorman, A. C.; Loveless, M. O.; Furher, J.; Satten, G. A.; Aschman, D. J.; Holmberg, S. D. *N. Engl. J. Med.* 1998, 338, 853).

10 Unfortunately, not all patients are responsive and a large number fail this therapy. In fact, approximately 30-50% of patients ultimately fail combination therapy. Treatment failure in most cases is caused by the emergence of viral resistance. Viral resistance in turn is caused by the rapid turnover of HIV-1 during the course of infection combined with a 15 high viral mutation rate. Under these circumstances incomplete viral suppression caused by insufficient drug potency, poor compliance to the complicated drug regimen as well as intrinsic pharmacological barriers to exposure provides fertile ground for resistance to emerge. More disturbing are recent findings which suggest that low-level replication 20 continues even when viral plasma levels have dropped below detectable levels (< 50 copies/ml) (Carpenter, C. C. J.; Cooper, D. A.; Fischl, M. A.; Gatell, J. M.; Gazzard, B. G.; Hammer, S. M.; Hirsch, M. S.; Jacobsen, D. M.; Katzenstein, D. A.; Montaner, J. S.; Richman, D. D.; Saag, M. S.; Schechter, M.; Schoolery, R. T.; Thompson, M. A.; Vella, S.; Yeni, P. G.; 25 Volberding, P. A. *JAMA* 2000, 283, 381). Clearly there is a need for new antiviral agents, preferably targeting other viral enzymes to reduce the rate of resistance and suppress viral replication even further.

30 HIV expresses three enzymes, reverse transcriptase, an aspartyl protease and integrase, all of which are potential antiviral targets for the development of drugs for the treatment of AIDS. However, integrase

stands out as being the only viral enzyme not targeted by current therapy. The integrase enzyme is responsible for insertion of the viral cDNA into the host cell genome, which is a critical step in the viral life cycle. There are a number of discrete steps involved in this process including

5 processing of the viral cDNA by removal of two bases from each 3'-terminus and joining of the recessed ends to the host DNA. Studies have shown that in the absence of a functional integrase enzyme HIV is not infectious. Therefore, an inhibitor of integrase would be useful as a therapy for AIDS and HIV infection.

10 A number of inhibitors of the enzyme have been reported. These include, nucleotide-based inhibitors, known DNA binders, catechols and hydrazide containing derivatives (Neamati, N.; Sunder, S.; Pommier, Y., *Drug Disc. Today*, 1997, 2, 487). However, no clinically active compound has resulted from these leads. Thus, what is needed is a clinically

15 effective inhibitor of the HIV integrase enzyme.

Formula Ia

15

In Formula Ia, R¹, R², R³, R⁴, R⁵, R⁶, R⁷, R⁸, R⁹ and R¹⁰ are as defined for Formula I, whereas B² is

20

The present invention further relates to a method of treating patients infected by the HIV virus, or of treating AIDS or ARC, by administering to the patient an effective amount of a compound of

Structural Formula Ia, or a pharmaceutically acceptable salt, solvate or prodrug thereof.

10 Detailed Description of the Invention

In the present invention, unless otherwise specified the following definitions apply.

The numbers in the subscript after the symbol "C" define the 15 number of carbon atoms a particular group can contain. For example, "C₁-C₆" means a substituent containing from one to six carbon atoms.

As used herein, the term "alkyl" means a saturated, straight chain or branched monovalent hydrocarbon radical having the stated number 20 of carbon atoms. Examples of such alkyl radicals include methyl, ethyl, n-propyl, isopropyl, n-butyl, isobutyl, sec-butyl, t-butyl and, where indicated, higher homologs and isomers such as n-pentyl, n-hexyl, 2-methylpentyl and the like. Haloalkyl refers to an alkyl radical that is substituted with one or more halo radicals, such as trifluoromethyl.

As used herein, the term "cycloalkyl" means a non-aromatic 3-6 membered ring. Examples include, cyclopropyl, cyclobutyl, cyclopentyl 25 and cyclohexyl.

Halo means chloro, bromo, iodo or fluoro.

"Aryl" means an aromatic hydrocarbon having from six to 14 carbon atoms; examples include phenyl and napthyl, indenyl, azulenyl, fluorenyl and anthracenyl.

The term "heterocyclic radical" refers to radicals derived from monocyclic saturated heterocyclic nuclei having 3-6 atoms containing 1-3 heteroatoms selected from nitrogen, oxygen or sulfur. Heterocyclic radicals include, for example, piperidinyl, piperazinyl, pyrrolidinyl and morpholinyl.

"Heteroaryl" means a five- or six-membered aromatic ring containing at least one and up to four non-carbon atoms selected from oxygen, sulfur and nitrogen. Examples of heteroaryl include 2-furyl, 3-furyl, 2-pyridyl, 3-pyridyl, 4-pyridyl, pyrazinyl, 2-thienyl, 3-thienyl, 10 pyrrolyl, oxazolyl, thiazolyl, imidazolyl, pyrazolyl, isoxazolyl, isothiazolyl, 1,2,3-oxadiazolyl, 1,2,3-triazolyl, 1,3,4-thiadiazolyl, pyridazinyl, pyrimidinyl, 1,3,5-triazinyl and 1,3,5-trithianyl.

In a preferred embodiment, compounds of the present invention that are useful for treating AIDS have the structure of Formula II.

Formula II

In Formula II, $R^1, R^2, R^3, R^4, R^5, R^6, R^7, R^8, R^9$ and R^{10} are as defined for Formula I, while B^2 is defined as in Formula Ia.

20 In yet another embodiment of the present invention, compounds having the structure of Formula III, as follows, are preferred chemical intermediates from which compounds, or pharmaceutically acceptable salts, solvates or prodrugs, useful for the treatment of AIDS are formed. Even more preferentially, the compounds of Formula III are useful, 25 themselves, as prodrugs and can be administered as a prodrug to a patient as a compound or in pharmaceutical formulation.

Formula III

In Formula III, R¹, R², R³, R⁴, R⁵, R⁶, R⁷, R⁸, R⁹, R¹⁰, R¹² and R¹³ are as

5 defined for Formula I.

In a more preferred embodiment, compounds of the present invention have the structure of Formula IV, shown below

10

Formula IV

wherein:

Each R¹⁴ is independently selected from

-CN,

-H, or

15 -halo;

R¹⁵ is

-CH₂C(O)N(CH₃)₂ or

-C₁-C₂ alkyl; and

B² is as defined for Formula Ia.

20 By virtue of its acidic moiety, where applicable, a compound of Formula I forms salts by the addition of a pharmaceutically acceptable base. Such base addition salts include those derived from inorganic bases which include, for example, alkali metal salts (e.g. sodium and potassium), alkaline earth metal salts (e.g. calcium and magnesium), aluminum salts and ammonium salts. In addition, suitable base addition

25

salts include salts of physiologically acceptable organic bases such as trimethylamine, triethylamine, morpholine, pyridine, piperidine, picoline, dicyclohexylamine, N,N'-dibenzylethylenediamine, 2-hydroxyethylamine, bis-(2-hydroxyethyl)amine, tri-(2-hydroxyethyl)amine, procaine, dibenzylpiperidine, N-benzyl-phenethylamine, dehydroabietylamine, N,N'-bishydroabietylamine, glucamine, N-methylglucamine, collidine, quinine, quinoline, ethylenediamine, ornithine, choline, N,N'-benzylphenethylamine, chloroprocaine, diethanolamine, diethylamine, piperazine, tris(hydroxymethyl)aminomethane and tetramethylammonium hydroxide and basic amino acids such as lysine, arginine and N-methylglutamine. These salts may be prepared by methods known to those skilled in the art.

15 Salts of an amine group may also comprise quaternary ammonium salts in which the amino nitrogen carries a suitable organic group such as an alkyl, alkenyl, alkynyl or arylalkyl moiety.

Compounds of Formula I, which are substituted with a basic group, may exist as salts formed through acid addition. The acid addition salts are formed from a compound of Formula I and a pharmaceutically acceptable inorganic acid, including but not limited to hydrochloric, hydrobromic, hydroiodic, sulfuric, phosphoric, or organic acid such as p-toluenesulfonic, methanesulfonic, acetic, benzoic, citric, malonic, fumaric, maleic, oxalic, succinic, sulfamic, or tartaric. Thus, examples of such pharmaceutically acceptable salts include chloride, bromide, iodide, sulfate, phosphate, methanesulfonate, citrate, acetate, malonate, fumarate, sulfamate, and tartrate.

Certain compounds of Formula I, and their salts, may also exist in the form of solvates with water, for example hydrates, or with organic solvents such as methanol, ethanol or acetonitrile to form, respectively, a

methanolate, ethanolate or acetonitrilate. The present invention includes each solvate and mixtures thereof.

This invention also encompasses pharmaceutically acceptable prodrugs of the compounds of Formula I. Prodrugs are derivatives of the 5 compounds of the invention which have chemically or metabolically cleavable groups and become, by solvolysis or under physiological conditions, the compounds of the invention which are pharmaceutically active in vivo. A prodrug of a compound of Structural Formula I may be formed in a conventional manner with a functional group of the 10 compounds such as with an amino, hydroxy or carboxy group. The prodrug derivative form often offers advantages of solubility, tissue compatibility, or delayed release in a mammalian organism (see, Bundgaard, H., Design of Prodrugs, pp. 7-9, 21-24, Elsevier, Amsterdam 1985). Prodrugs include acid derivatives well known to practitioners of 15 the art, such as, for example, esters prepared by reaction of the parent acidic compound with a suitable alcohol, or amides prepared by reaction of the parent acid compound with a suitable amine. Simple aliphatic or aromatic esters derived from acidic groups pendent on the compounds of this invention are preferred prodrugs. In some cases it is desirable to 20 prepare double ester type prodrugs such as (acyloxy) alkyl esters or (alkoxycarbonyl)oxy)alkyl esters. Examples of prodrugs of compounds of the present invention include the compounds 1-A, 2-A, 3-C, 4-B, 5-B, 6-C, 7-C, 8-C, 9-C, 10-A, 11-C, 12-C, 13-C, 14-C, 15-C, 16-C, 17-C, 18-C, 19-C, 20-C, 21-C, 22-A, 22-B, 23-C, 25-C, 26-C, 27-C, 28-C, 29, 30-C, 31-C, 32-D, 25 32-E, 33, 34-C, 35-C, 36, 37-D, 38-61.

In addition, a compound of Structural Formula I, or a salt, solvate or prodrug thereof, may exhibit polymorphism. The present invention also encompasses any such polymorphic form.

Certain compounds of Structural Formula I may contain one or 30 more chiral centers and exist in different optically active forms. When

compounds of Structural Formula I contain one chiral center, the compounds exist in two enantiomeric forms. The present invention includes both enantiomers and mixtures of enantiomers such as racemic mixtures. The enantiomers may be resolved by methods known to those skilled in the art, for example, by formation of diastereoisomeric salts which may be separated by crystallization, gas-liquid or liquid chromatography, selective reaction of one enantiomer with an enantiomer-specific reagent. It will be appreciated that where the desired enantiomer is converted into another chemical entity by a separation technique, then an additional step is required to form the desired enantiomeric form. Alternatively, specific enantiomers may be synthesized by asymmetric synthesis using optically active reagents, substrates, catalysts or solvents, or by converting one enantiomer into the other by asymmetric transformation.

15 Certain compounds of Structural Formula I may also exist in different stable conformational forms which may be separable. Torsional asymmetry due to restricted rotation about an asymmetric single bond, for example because of steric hindrance or ring strain, may permit separation of different conformers. The present invention includes each conformational isomer of compounds of Structural Formula I and mixtures thereof.

20 Certain compounds of Structural Formula I may exist in zwitterionic form and the present invention includes each zwitterionic form of compounds of Structural Formula I and mixtures thereof.

25 The compounds of this invention can also exist as tautomers; therefore the present invention also includes all tautomeric forms.

30 The compounds of Formula Ia are useful in the inhibition of HIV integrase, the prevention or treatment of infection by the human immunodeficiency virus and the treatment of consequent pathological conditions such as AIDS or ARC. The treatment involves administering to

a patient, in need of such treatment, a compound of Formula Ia, or a pharmaceutically acceptable salt, solvate or prodrug thereof, or a pharmaceutical composition comprising a pharmaceutical carrier and a therapeutically effective amount of a compound of the present invention,
5 or a pharmaceutically acceptable salt, solvate or prodrug therefor.

It will be appreciated by those skilled in the art that reference herein to treatment extends to prophylaxis as well as the treatment of established infections or symptoms. This includes initiating treatment pre- and post-exposure to the virus. In addition, the present invention
10 can be administered in conjunction with other anti-HIV agents (HIV protease inhibitors, nucleoside reverse transcriptase inhibitors, non-nucleoside reverse transcriptase inhibitors, and HIV-entry inhibitors), immunomodulators, antiinfectives and/or vaccines.

The compounds of the present invention are also useful in the
15 preparation and execution of screening assays for antiviral compounds. Further, the compounds of the present invention are useful in establishing or determining the binding site of other antiviral compounds to HIV integrase, for example, by competitive inhibition.

The compounds of the present invention may be administered
20 orally, parenterally (including subcutaneous injections, intravenous, intramuscular, intrasternal injection or infusion techniques), by inhalation spray or rectally, in dosage unit formulations containing conventional non-toxic pharmaceutically acceptable carriers, adjuvants and vehicles.

This invention also provides a pharmaceutical composition for use
25 in the above described therapeutic method. A pharmaceutical composition of the present invention comprises an effective amount of a compound of Formula I in association with a pharmaceutically acceptable carrier, excipient or diluent.

The active ingredient in such formulations comprises from 0.1
30 percent to 99.9 percent by weight of the formulation. By

"pharmaceutically acceptable" it is meant that the carrier, diluent or excipient must be compatible with the other ingredients of the formulation and not deleterious to the recipient thereof.

The present pharmaceutical compositions are prepared by known procedures using well known and readily available ingredients. The compositions of this invention may be formulated so as to provide quick, sustained or delayed release of the active ingredient after administration to the patient by employing procedures well known in the art. In making the compositions of the present invention, the active ingredient will usually be admixed with a carrier, or diluted by a carrier, or enclosed within a carrier which may be in the form of a capsule, sachet, paper or other container. When the carrier serves as a diluent, it may be a solid, semi-solid or liquid material which acts as a vehicle, excipient or medium for the active ingredient. Thus, the compositions can be in the form of tablets, pills, powders, beadlets, lozenges, sachets, elixers, suspensions, emulsions, solutions, syrups, aerosols, (as a solid or in a liquid medium), soft and hard gelatin capsules, suppositories, sterile injectable solutions, sterile packaged powders and the like.

The compounds can be administered by a variety of routes including oral, rectal, transdermal, subcutaneous, intravenous, intramuscular and intranasal.

When administered orally, these compositions are prepared according to techniques well-known in the art of pharmaceutical formulation. For oral administration, the compound is typically formulated with excipients such as binders, fillers, lubricants, extenders, diluents, disintegration agents and the like as are known in the art.

For parenteral administration, the compound is formulated in pharmaceutically acceptable non-toxic, parenterally-acceptable diluents or solvents, such as mannitol, 1,3-butanediol, water, 5 percent dextrose, Ringer's solution or isotonic sodium chloride solution, or suitable

dispersing or wetting and suspending agents, such as sterile, bland, fixed oils, including synthetic mono- or diglycerides, and fatty acids, including oleic acid.

A compound of the present invention, or a salt or solvate thereof,

5 can be formulated in unit dosage formulations comprising a dose between about 0.1 mg and about 1000 mg, or more, according to the particular treatment involved. An example of a unit dosage formulation comprises 5 mg of a compound of the present invention in a 10 mL sterile glass ampoule. Another example of a unit dosage formulation comprises about 10 10 mg of a compound of the present invention as a pharmaceutically acceptable salt in 20 mL of isotonic saline contained in a sterile ampoule.

The compounds of the present invention can also be administered to humans in a dosage range of 1 to 100 mg/kg body weight in divided doses. One preferred dosage range is 1 to 20 mg/kg body weight orally 15 in divided doses. It will be understood, however, that the specific dose level and frequency of dosage for any particular patient may be varied and will depend upon a variety of factors including the activity of the specific compound employed, the metabolic stability and length of action of that compound, the route of administration, the age, body weight, 20 general health, sex, diet, mode and time of administration, rate of excretion, drug combination, the severity of the particular condition, and the host undergoing therapy.

General methods useful for the synthesis of compounds embodied in this invention are shown below. The preparations shown below are 25 disclosed for the purpose of illustration and are not meant to be interpreted as limiting the processes to make the compounds by any other methods.

It will be appreciated by those skilled in the art that a number of methods are available for the preparation of the compounds of the 30 present invention as provided by Structural Formula I. A compound of

Structural Formula I may be prepared by processes which include processes known in the chemical art for the production of structurally analogous compounds or by a novel process described herein. A process for the preparation of a compound of Structural Formula I (or a 5 pharmaceutical acceptable salt thereof) and novel intermediates for the manufacture of a compound of Formula I, as defined above, provide further features of the invention and are illustrated by the following procedures in which the meanings of the generic radicals are as defined above, unless otherwise specified. It will be recognized that it may be 10 preferred or necessary to prepare a compound of Formula I in which a functional group is protected using a conventional protecting group, and then to remove the protecting group to provide the compound of Formula I.

Thus, there is provided a process for preparing a compound of 15 Formula I (or a pharmaceutically acceptable salt thereof) as provided in any of the above descriptions which is selected from any of those described in the examples, including the following.

Schemes I and II illustrate the synthesis of non-commercially available N,O-disubstituted hydroxylamines I-C and II-C. In Scheme I 20 benzaldehyde, I-A, substituted with 1-3 R³ groups is condensed with hydroxylamine or an O-substituted hydroxylamine derivative. In the event that the hydroxyl group is unsubstituted (R² = H), this position can be functionalized via nucleophilic attack on an appropriately substituted R²-X electrophile (X = Cl, Br, I, -OTs, -OMs or -OTf). It will be 25 appreciated by those skilled in the art that this reaction can be conducted in a number of different ways. The resulting oxime I-B can be easily reduced to the corresponding N,O-disubstituted hydroxylamine using sodium cyanoborohydride, or a related reducing agent such as triethylsilane, under acidic conditions. In Scheme II, an O-substituted 30 hydroxyl amine is acylated with Boc-anhydride to form intermediate II-A.

This can be reacted with an appropriately substituted R^1CH_2-X electrophile ($X = Cl, Br, I, -OTs, -OMs$ or $-OTf$) under basic conditions to yield the Boc-protected N-,O-disubstituted hydroxylamine II-B. The Boc-protecting group is removed to yield N-,O-disubstituted hydroxylamine II-C. It will be appreciated by those skilled in the art that other protecting groups or acylating agents can be used in place of the Boc-group to effect the same transformation.

Scheme II

As shown in Scheme III, the N,O-disubstituted hydroxylamines
 5 are then coupled to dioxolane III-A or III-B using standard amide bond
 forming chemistry. The syntheses of the dioxolanes III-A and III-B are
 described in the exemplification section. The resulting intermediates III-C
 and III-D are saponified with NaOH or LiOH to yield integrase inhibitors
 III-E and III-F.

Scheme III

5 Alternative synthetic methods useful for producing the
 compounds described in this invention are illustrated in Scheme IV. The
 acylated N,O-disubstituted hydroxylamine IV-A can be synthesized
 starting directly from II-C, synthesized as shown previously or via a
 different route which commences with compound IV-C. IV-C can be
 10 reacted with N,O-bis-Boc-hydroxylamine to yield intermediate IV-D.

After removal of the Boc-protecting groups this is acylated with acetyl chloride or acetic acid anhydride under standard amide bond forming conditions to produce IV-F. The hydroxyl group is then functionalized via nucleophilic substitution of an appropriately activated R²-X (X = Cl, 5 Br, I, -OTs, -OMs or OTf) yielding IV-A. This intermediate is condensed with dimethyl oxalate in a Claisen reaction carried out using lithium bis(trimethylsilyl)amide. Ester IV-B is saponified using NaOH or LiOH to yield integrase inhibitors III-F.

Scheme IV

Starting from intermediate 20-C, Scheme V, illustrates the synthesis of compounds 20, 22-A, 22-B, 22 and 24.

Scheme V

5

In Scheme VI compound 22-A is converted to the corresponding acid chloride, compound 38-A, using oxalyl chloride. This is 10 subsequently reacted with amine VI-A using a suitable base catalyst to yield intermediate VI-B. This intermediate is hydrolyzed under basic conditions (LiOH) to produce inhibitors VI-C.

5 Exemplification

The specific examples that follow illustrate the syntheses of the compounds of the instant invention, and are not to be construed as limiting the invention in sphere or scope. The methods may be adapted to variations in order to produce compounds embraced by this invention

10 but not specifically disclosed. Further, variations of the methods to

produce the same compounds in somewhat different manner will also be evident to one skilled in the art.

In the following experimental procedures, all temperatures are understood to be in Centigrade (C) when not specified. The nuclear magnetic resonance (NMR) spectral characteristics refer to chemical shifts (δ) expressed in parts per million (ppm) versus tetramethylsilane (TMS) as reference standard. The relative area reported for the various shifts in the proton NMR spectral data corresponds to the number of hydrogen atoms of a particular functional type in the molecule. The nature of the shifts as to multiplicity is reported as broad singlet (bs or br s), broad doublet (bd or br d), broad triplet (bt or br t), broad quartet (bq or br q), singlet (s), multiplet (m), doublet (d), quartet (q), triplet (t), doublet of doublet (dd), doublet of triplet (dt), and doublet of quartet (dq). The solvents employed for taking NMR spectra are acetone-d₆ (deuterated acetone), DMSO-d₆ (perdeuteriodimethylsulfoxide), D₂O (deuterated water), CDCl₃ (deuteriochloroform) and other conventional deuterated solvents.

The abbreviations used herein are conventional abbreviations widely employed in the art. Some of which are: calcd (calculated); DMSO (dimethylsulfoxide); EtOAc (ethyl acetate); HPLC (high-pressure liquid chromatography); LC/MS (liquid chromatography, mass spectroscopy); LDA (lithium diisopropyl amide); LiHMDS (lithium bis(trimethylsilyl)amide); SiO₂ (silica gel); THF (tetrahydrofuran), TFA (trifluoroacetic acid), Me (methyl), Et (ethyl), Ph (phenyl), tBuOK (potassium tert-butoxide), NaOMe (sodium methoxide), NaOEt (sodium ethoxide), Boc (tert-butoxycarbonyl), and DEAD (diethylazodicarboxylate).

The table below shows the percent inhibition of HIV-integrase in the presence of 50 μ M compounds 1-24 and 62-79. For each reaction, 5 pmole of biotin labeled substrate DNA was bound to 100ug of Streptavidin coated PVT SPA beads (Amersham Pharmacia Biotech). 0.26 ng of recombinant integrase was incubated with the beads for 90 min at 37C. Unbound enzyme was removed by washing the complex followed by addition of inhibitors and 0.1 fmol of P33 labeled target DNA.

10 Reaction was stopped by adding EDTA to a final concentration of 10 mM. Samples were counted in TopCountNXT (Packard) and the CPM was used as a measure of integration. Reaction condition was as described in A. Engelman and R. Craigie, J. Virol. 69, 5908-5911 (1995). The sequences of substrate and target DNA were described in Nucleic Acid Research 22,1121-1122 (1994). Compounds of this invention tested in this assay have IC₅₀'s of approximately 0.01 to 50 μ M

Inhibition of HIV replication

Cell culture assays were performed using a single cycle, recombinant HIV virus expressing Renilla luciferase. Anti-viral activity was evaluated by measuring the production of luciferase in the infected cells 5 days post-infection. Susceptibility of the virus to compounds was determined by incubation in the presence of the serially-diluted compound. The 50% effective concentration (EC₅₀) was calculated by using the exponential form of the median effect equation where (Fa) = 1/[1+ (ED₅₀/drug conc.)^m]. Compounds of this invention tested in this assay have EC₅₀'s of approximately 0.02 to 50 μ M. The table below shows the percent viral inhibition at a compound concentration of 1.6 μ M for a set representative compounds.

EXAMPLE 41Hydrolysis of Prodrugs Under Physiological Conditions

As shown in Scheme VII, compounds of Formula VII-A wherein R¹ and R² are as defined for Formula I, are hydrolyzed at pH 7 (37 °C) to

yield the corresponding 2-hydroxy acrylic, VII-B, and are thus useful as prodrugs.

Scheme VII

5

In an experiment to measure the hydrolysis of compounds such as VII-A, compound 3-C was added to 25mM phosphate buffer (pH 7) at a concentration of 0.03 mg/mL. The reaction was incubated at 37°C for a period of 24 hours. Interval time points are analyzed by HPLC, identifying both the compound 3-C and compound 3, the parent acid. Results are shown in the table.
